

The Remote Peering Jedi

A portal in the remote peering ecosystem

RIPE
73
24 - 28 OCT 2016
MADRID, SPAIN

Marios Isaakidis, UCL, marios.isaakidis.15@ucl.ac.uk

Edwards Mukasa, NFT Consult, edwards.mukasa@nftconsult.com

Motivation

- Knowing which peers allows better-informed peer selection process and higher transparency.
- Operational concerns:
 - Added latency and troubleshooting complexity
 - Routing inefficiencies
 - Invisible Layer-2 intermediaries
 - Network economics and business models

Castro, Ignacio, Juan Camilo Cardona, Sergey Gorinsky, Pierre Francois.
"Remote peering: More peering without internet flattening."
ACM CoNEXT 2014.

Methodology

- Parse traceroute paths and detect IXP hops according to traIXroute
- Calculate the RTT between the IXP far-end and near-end peers:

$$\text{RTT of IXP link: } \text{RTT}_3 - \text{RTT}_2$$

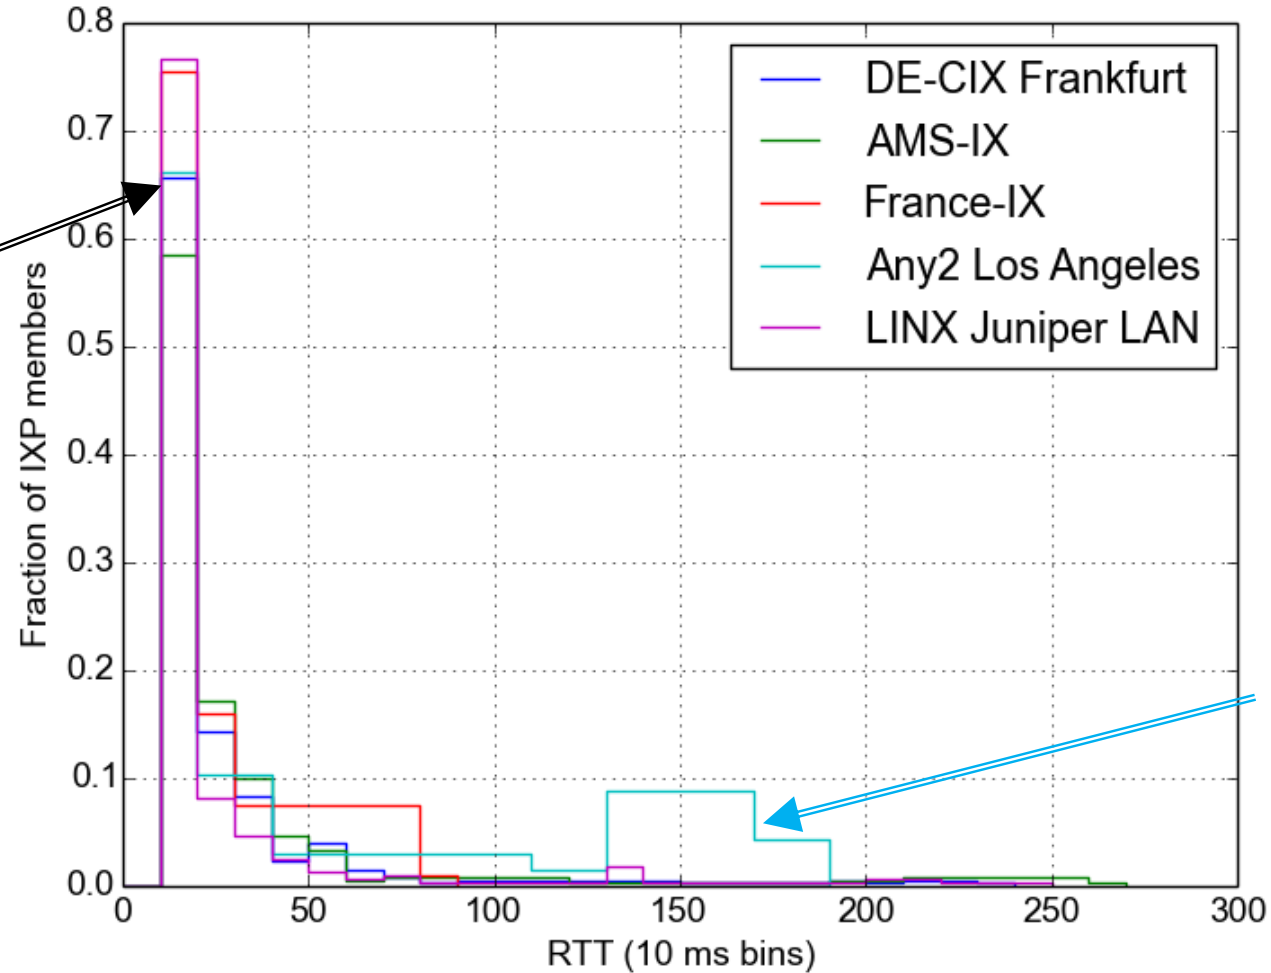

Robust RTT estimations

- Latency estimation from traceroute can be noisy

BUT

- RIPE Atlas offers a massive corpus of traceroute paths from diverse vantage points
 - Multiple observations allow us to remove outliers and de-noise
- For every pair of near-end IP, far-end IXP we require at least 50 paths from which we calculate the median RTT difference.
- Take bottom 50% of lower percentile of RTTs, infer remote peering if $\text{Median_RTT_diff} \geq 20 \text{ ms}$

Results

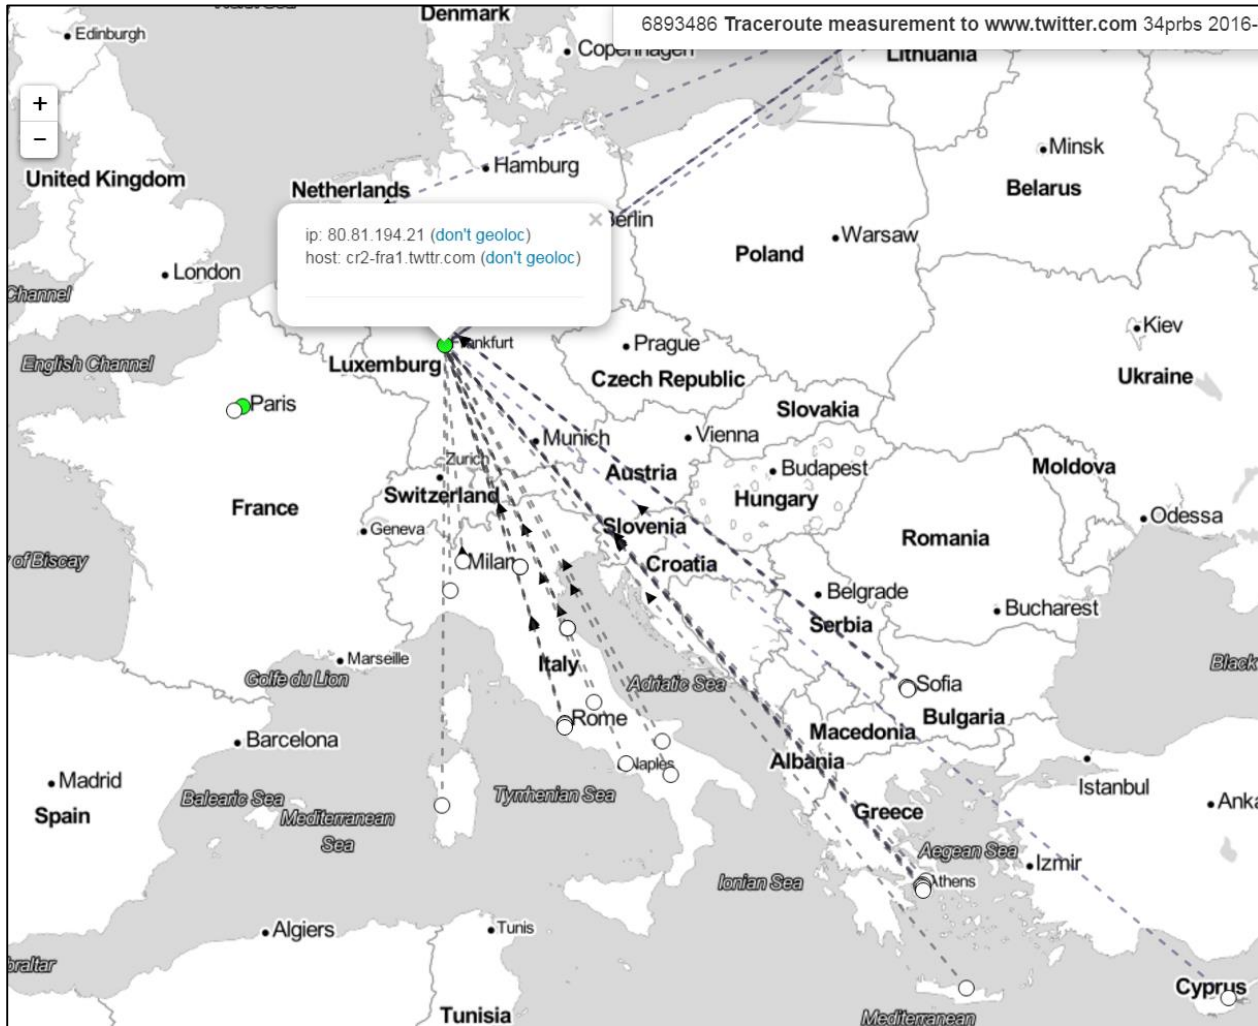

~60-75% ≤ 10 ms
(definitely local peers)

Trans-pacific
remote peers of
Any2 Los Angeles

Validation

- We collected validation data for the latencies from three large IXPs (RTT_{IXP}) and compared it against the RTTs estimated through Atlas (RTT_{ATLAS}):
 - AMS-IX (ARPing from inside the IXP)
 - DE-CIX (Ping from inside the IXP)
 - France-IX (Ping from inside the IXP)
- True positive if $RTT_{IXP} \geq 20ms$ and $RTT_{ATLAS} \geq 20ms$
 - France-IX: 99%
 - DE-CIX: 99%
 - AMS-IX: 97%

Remote peerings used to access large CDNs

Traceroutes to twitter.com and reddit.com from top-10 remote peers

The usual suspects

- Remote peers tend to peer remotely at multiple IXPs

Autonomous System	Location	Remote presences
AS20485 (TransTelekom)	Moscow RU	AMS-IX, DE-CIX, LINX, France-IX, PLIX, Equinix Ashburn
AS8262 (Evolink)	Sofia BG	AMS-IX, DE-CIX, LINX, France-IX
AS31042 (Serbia Broadband)	Belgrad RS	AMS-IX, DE-CIX, LINX, France-IX
AS7713 (Telin)	Hong Kong HK	AMS-IX, DE-CIX, LINX, Any2 LA
AS52320 (GlobeNet)	Miami FL US	AMS-IX, DE-CIX, LINX, Equinix Ashburn
AS12578 (LatTelecom)	Riga LV	AMS-IX, DE-CIX, LINX,MSK-IX
AS1267 (Wind)	Milan IT	AMS-IX, DE-CIX, LINX
AS8866 (VivaComm)	Sofia BG	AMS-IX, DE-CIX, LINX
AS45352 (IPSERVERONE)	Singapore SG	AMS-IX, DE-CIX, LINX
AS6866 (CYTA)	Nicosia CY	AMS-IX, DE-CIX, LINX

Interpreting the facility information provided in PeeringDB

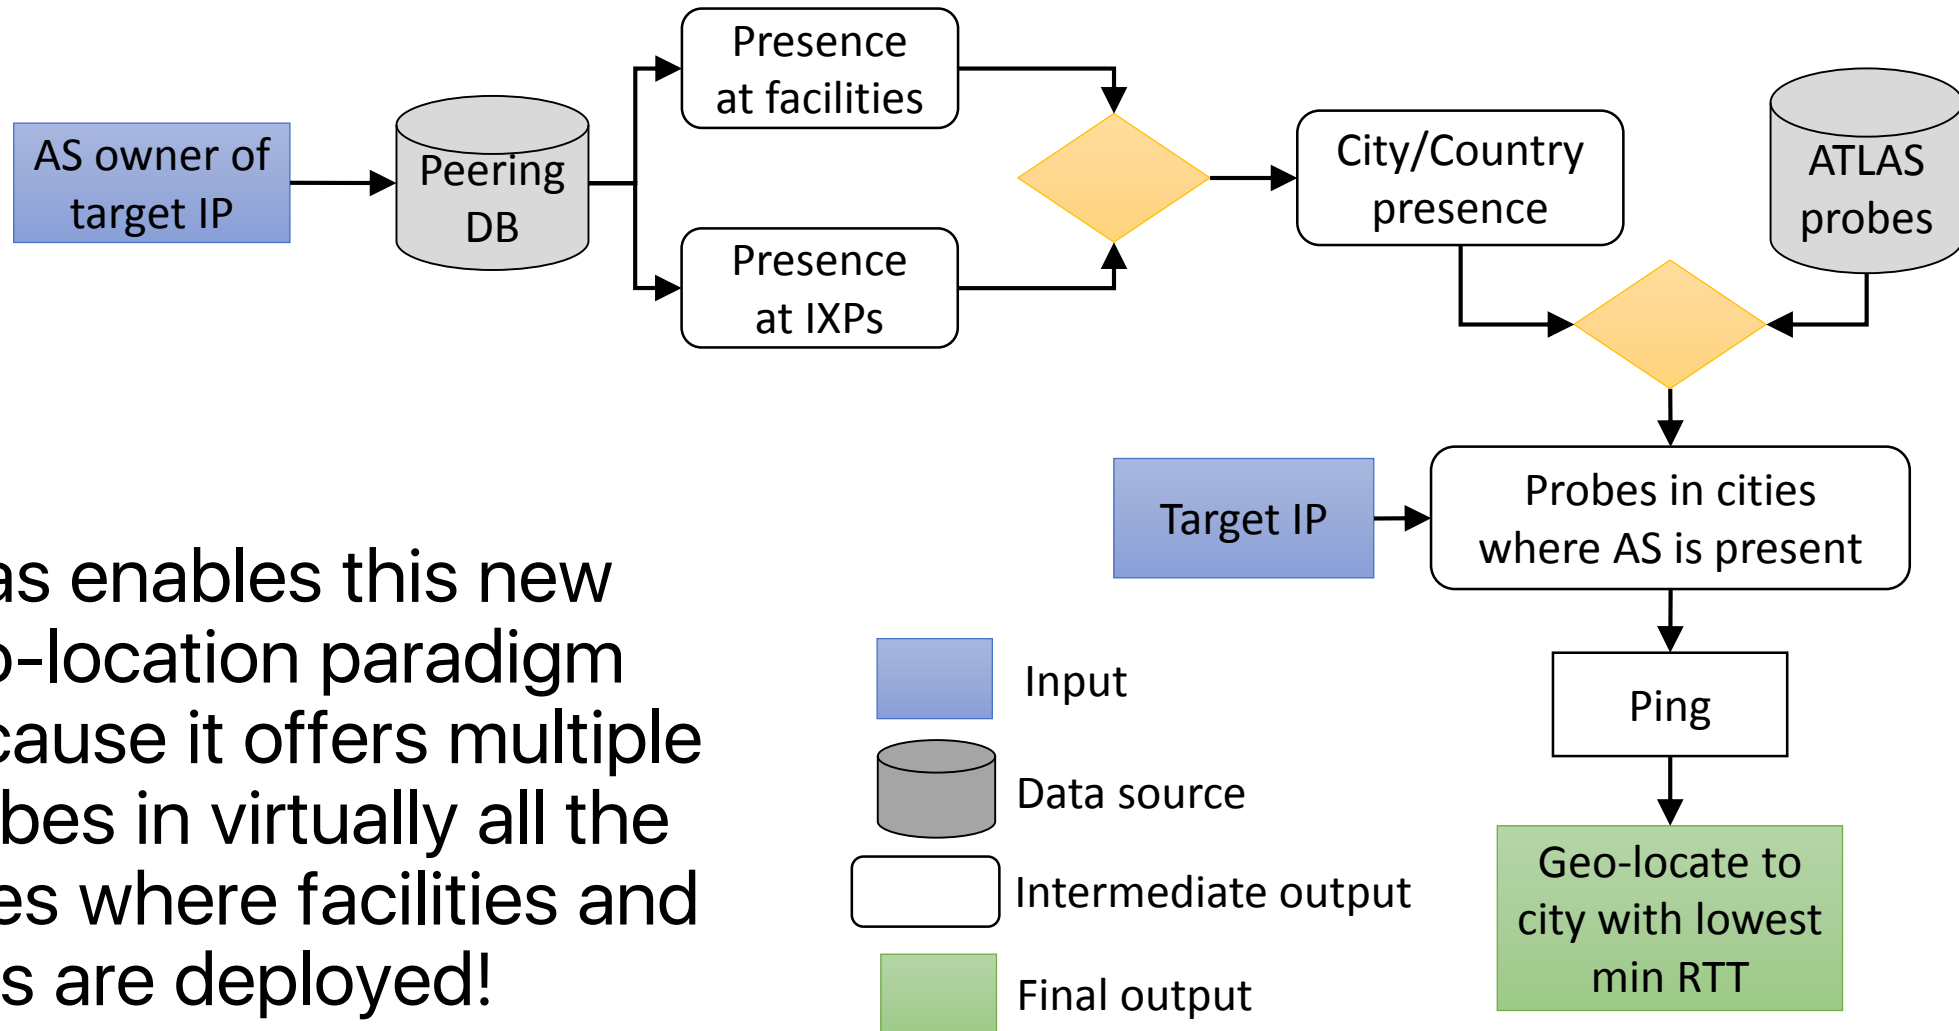

- Detecting remote peering at IXPs provides an indirect way to interpret the facility information provided by ASes in PeeringDB
- Percentage of remote peers claiming to have local presence at the IXP:
 - AMS-IX: 16%
 - LINX: 20%
 - DE-CIX: 25%
- ASes may record facility presence not to indicate tenancy but their availability for private interconnections over the facility.
- ASes may record inaccurate information by mistake or to appear more appealing peers.

Where are the city-level locations of the remote peers?

Presence-informed RTT Geo-location

- Most of the available accurate geo-location methods can resolve only a subset of the remote peering IPs:
 - **OpenIP Map**: self-reported data, covers only a subset of the IPs
 - **DNS-based geo-location**: cannot be applied to addresses without reverse DNS record
- Other geo-location methodologies not available or too error prone:
 - **Trilateration**: high complexity, errors for regions with many large metro areas close to each other (e.g. West/Central Europe).
 - **Geo-location databases**: Very inaccurate for router geo-location
- **Key intuition**: reduce the problem space by exploiting the fact that the IPs of a given AS can be where the AS has presence.

Presence-informed RTT Geolocation: Methodology

Presence-informed RTT Geolocation: Example
