

# Scamper remote control

Matthew Luckie  
mjl@wand.net.nz

# Overview of scamper

- Powerful open-source packet-prober
  - **Precise**: stores details (warts, warts2json)
  - **Parallelized**: event-driven simultaneous measurement
  - **Portable**: UNIX-like systems, MacOS, Windows
  - **Flexible**: standalone vs. coordination+control
  - **Volunteer friendly**: standalone, low resource requirements
  - **Modular**: extensible, but supports most popular active measurements (traceroute, ping, alias resolution, tbit)
  - **Documented**: 48 pages of man pages (16 for scamper itself)
- Users: CAIDA, Dyn, many other researchers.
- Contact: Matthew Luckie [mjl@wand.net.nz](mailto:mjl@wand.net.nz)

# Interactive Control in Scamper

- Scamper has a “control socket” since 2004:
  - TCP socket listening on loopback interface
    - `scamper -P <port>`
  - Unix domain socket listening in file system
    - `scamper -U <unix-socket-filename>`
- Control socket:
  - Control macroscopic behavior of scamper, or
  - Schedule and receive measurement responses

# scamper measurement drivers

# Interactive measurements in scamper

- We used the control socket for intelligent measurement control in research, e.g.:
- `sc_filterpolicy` (NDSS2016):
  - for a list of dual-stack systems, check each IP address for [congruent filtering policy](#)
- `sc_tbitblind` (IMC2015):
  - for a list of web servers and routers, [test resilience to blind TCP attacks](#)
- `sc_trlinks` (PAM2014):
  - traceroute a set of destinations, and [infer if observed IP-links are point-to-point](#)

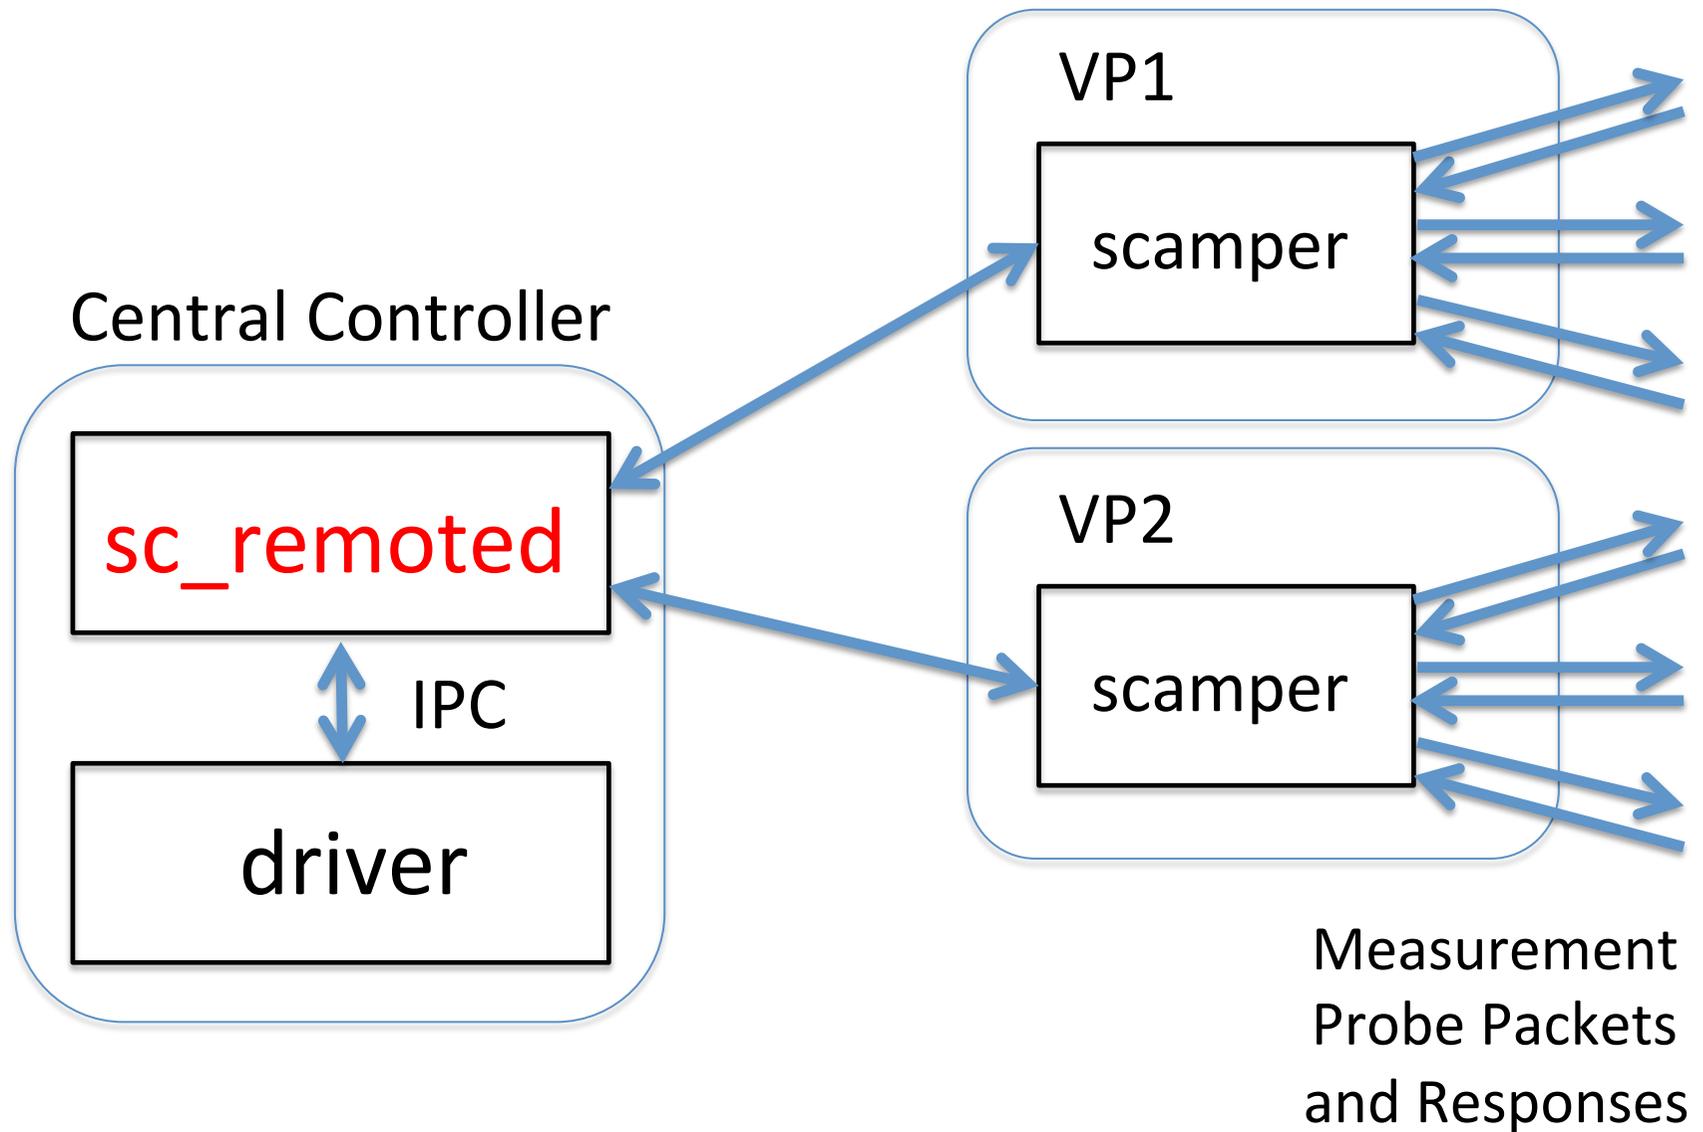

# Why add remote control?

- Original scamper motivation was to build a stand-alone packet prober
  - i.e., avoid centralized controller issues
  - at the time, other infrastructures seemed to couple prober with control
  - never going to please everyone
- Prompted by Ethan and David's reboot of reverse traceroute, I built remote control functionality into scamper

# Why add remote control?

- Researchers and operators may use low-resource nodes for complex measurements
  - scamper drivers might need more memory to keep state than VP has available

# Using scamper remote control

# Using scamper remote control

- `sc_remoted` exposes remote scamper instances as Unix domain sockets
  - One socket per remote VP
- Supports TLS
  - CA certificate built into scamper for validation
- VP naming
  - Scamper instance can supply monitor name to allow identification of remote nodes

# Remote measurements in scamper

```
$ echo "ping -c 1 8.8.8.8" |  
  sc_attach -i - -o - -R  
    OWXXXXXXXXXXXX-98.204.x.x\:39742 |  
  sc_warts2json  
{ "version": "0.4", "type": "ping", "method": "icmp-echo",  
  "src": "98.204.x.x", "dst": "8.8.8.8", "start": { "sec":  
1455140484, "usec": 827228 }, "ping_sent": 1,  
  "probe_size": 84, "userid": 0, "ttl": 64, "wait": 1,  
  "timeout": 1, "responses": [ { "from": "8.8.8.8", "seq": 0,

  "icmp_code": 0 } ], "statistics": { "replies": 1, "loss": 0,  
  "min": 19.510, "max": 19.510, "avg": 19.510, "stddev":  
0.000 } }
```

# Experience so far

- Reverse traceroute reboot:
  - Will leave comments on their experience with scamper's remote control to Ethan and Dave
- Border mapping of networks:
  - Incorporated Project BISmark nodes into set of VPs to infer interdomain router involving the network hosting the VP
  - 3.5MB memory, 1-3% CPU on BISmark (64-128MB memory, 400Mhz MIPS CPU)
  - 150MB memory, 0% CPU on controller per driver
